Outline

Nicholas Pappas   2

1. Introduction

Information systems are more capable today than ever before. Society increasingly relies on computing environments ranging from simple home networks, commonly attached to high speed Internet connections, to the largest enterprise networks spanning the entire globe. Filling one's tax return, shopping online, banking online, or even reading news headlines posted on the Internet are all so convenient. This increased reliance and convenience, coupled with the fact that attacks are concurrently becoming more prevalent has consequently elevated the need to have security controls in place to minimize risk as much as possible.

This risk is often ignored as many people mistakenly disregard the computing power of their home systems, or small office networks. If the risk is not completely ignored, system owners routinely deploy a network firewall to protect web servers, or email servers and mistakenly feel safe. The convenience of conducting business over the world wide web, or communicating over email has made such services a prime target for automated attacks. Most network firewalls control network access by blocking traffic based on an IP address and port number. If you have an email server and wish for it to communicate with systems external to your network you will have to open port 25 (smtp) enabling this external communication. But what happens when an inbound attack comes in over port 25? Without having devices designed to monitor the content of this malicious traffic the email server is at the mercy of such an attack.

Nicholas Pappas 3

This document introduces tools used to systematically monitor network activity and discusses the deployment strategies of such systems. Regardless of the size of the network, having the ability to monitor network activity is a key component of defending information systems from attacks launched through various networks as well as finding internal systems that may not be configured correctly resulting in extraneous traffic absorbing valuable network throughput. We begin with an introduction of what network intrusion detection systems and intrusion prevention systems are, then discuss connecting and deploying such devices. The paper then concludes after mentioning examples utilizing these systems in practical environments. There is no single security measure sufficient to independently protect information systems. Having a layered security architecture greatly reduces risk to system users. One invaluable layer is comprised of network intrusion detection systems.

2.Network Intrusion Detection System (IDS)

Network Intrusion Detection Systems (IDS) monitor system behavior and alert on potentially malicious network traffic (Baker, 2004). IDS can be set inline, attached to a spanning port of a switch, or make use of a hub in place of a switch. The idea here is to allow access to all packets you wish the IDS to monitor.

While copious amounts of traffic can be monitored, the key is for the system to only alert on events of interest. When IDS raise an over abundance of alerts usefulness and trust in the system are reduced. When the system constantly gives

Nicholas Pappas   4

false alarms, alerts tend to not be taken seriously. On the other side of the spectrum, if the IDS rarely alerts on malicious traffic, it leads one to wonder if it is working at all. Tuning an IDS is somewhat of an art, a balancing act between four points of concern. These four points are true positives, false positives, true negatives and false negatives. Table 1 shows their relationship:

	POSITIVE	NEGATIVE
TRUE	True Positive: Alerted on intrusion attempt	True Negative: Not alerted on benign activity
FALSE	False Positive: Alerted on benign activity	False Negative: Not alerted on intrusion attempt

Table 1: Relationship of event categories.

The ideal tuning of an IDS maximizes instances of events categorized in the cells with a shaded background. *True positives* occur when the system alerts on intrusion attempts or other malicious activity. False negatives are somewhat of a null situation but are important nonetheless. The *false negative* is comprised of the system failing to alert on malicious traffic. At times many people have trouble remembering what each of the four event categories are. An analogy helps.

Imagine the life cycle of a schoolhouse fire alarm. Using this analogy to describe the four categories is perhaps an easier method of understanding the distinctions. A true positive, would then be analogous to a burning schoolhouse and the alarm sounding. This, after all, is the intended purpose of the schoolhouse fire alarm. The false negative occurs when the schoolhouse has an actual fire yet the fire

Nicholas Pappas   5

alarm remains silent; alerting no one of the fire thus creating a danger to those counting on successful operation of the fire alarm.

Continuing with this analogy, the remaining conditions are as follows. When a mischievous student pulls the alarm, knowing no fire exists, he/she presents a false positive. The alarm dutifully goes off with the lack of a fire. Numerous occurrences of false positives and the seriousness of the alarm is belittled and soon to be ignored. Finally the true negative relates to the alarm remaining silent while the schoolhouse is not aflame. Table 2 maps the conditions of this analogy using a similar format used in Table 1.

	ALARM	SILENCE
Intended Function	True Positive: Alarm sounded during actual fire	True Negative: Alarm silent no actual fire
Broken Function	False Positive: Alarm sounded no actual fire	False Negative: Alarm silent during actual fire

Table 2: Relationships as they apply to the schoolhouse fire alarm analogy.

Tuning an IDS is typically an ongoing task. Threats and computing environments are ever-changing, thus systems deployed to detect such threats must adapt accordingly. Detecting malicious network activity is an important piece of an overall security architecture, but what can we do to defend from detected attacks? Prevention is the key and covered in the section.

Nicholas Pappas 6

3.Network Intrusion Prevention System (IPS)

The ability to monitor network traffic is a key component of protecting information systems. Even still, defending those systems from the many threats can be a daunting task. A firewall is commonly used to provide a layer of security for its respective local network. Firewalls by themselves have limitations though. Most can only block based on IP addresses or ports. In contrast Network Intrusion Prevention Systems (IPS) are able to use signatures designed to detect and defend from specific types of attacks such as denial of service attacks among others. This is an advantage, for instance, with sites hosting Web servers.

To permit Web service traffic, a firewall passes Hypertext Transfer Protocol (port 80) to external systems if not the entire world. This opens up risk because many attacks and exploits are inherent to Web server applications (e.g., Apache, Microsoft IIS). Even when the Web server is fully patched and well maintained, insecure Web applications all too often exist on a target Web server. Web applications themselves introduce additional risks (e.g., Cross-Site Scripting). Coupling a firewall with an IPS creates the potential to reduce these risks. An IPS is capable of monitoring the content deep inside the Web traffic. When the IPS discovers an event considered to be a true positive, the malicious connection is dropped and all subsequent matching packets are destined for the same outcome. In this ideal situation, the Web server never commits processing power to the malicious attack as it continues providing Web content to legitimate clients it was

Nicholas Pappas   7

intended to serve.

Web services are commonplace across the Internet, but the above example can be applied to many other networked services. To be compliant with systems across the wide spread internetwork a standard service port must be used. These ports are considered to be "known ports", for instance port 25 is assigned to Simple Mail Transport Protocol (SMTP), port 53 is assigned to Domain Network Services (DNS). Permitting these ports through a firewall is essential to be compatible with systems across the globe. Using an IPS along with a firewall offers the system owners some piece of mind while at the same time maintaining the required functionality.

IPS have also been known to block buffer overflow type attacks, and can be configured to report on network scans that typically signal a potential attack is soon to follow. Advanced usage of an IPS may not drop malicious packets but rather redirect specific attacks to a honeypot. A simple example of this utilization might redirect a malicious connection to a device setup to emulate the would be victim. Honeypots are not in the scope of this paper. However, this type of redirection creates research opportunities into methods of attackers or active automated threats, while at the same time defending the actual production systems. At the very least, the honeypot-redirect methodology creates potential to absorb attackers' time and other resources as systems under their command attempt to compromise phony assets.

Nicholas Pappas   8

4. Key Differences Between IDS & IPS

Intrusion detection and intrusion prevention are similar concepts but there are distinct differences, unique concerns, and benefits inherent with deploying either one, or both as we will see later. Let's start our dissection with intrusion detection.

Network intrusion detection systems allow analysts the ability to peer into network traffic and gain an in-depth understanding of protocols belonging to network stacks, applications and operating systems. While intrusion detection systems can be placed inline, they are commonly connected to the spanning port of a switch, attached to a hub, or make use of network taps. The intent here is to allow a designated network interface to process all traffic analysts want to inspect.

If an intrusion detection system is out-of-band, the opposite of inline, then the monitored network will not be at the mercy of the IDS failure potential. If the system is placed inline and it fails, network packets will no longer be processed thus ceasing all connectivity the system is designed to monitor. This is a benefit over intrusion prevention systems which are always configured inline.

Detection systems connected to a spanning port or hub have the potential to send a reset packet, to both the source and target of malicious sessions. This being an example of utilizing an IDS as a defensive measure. However, this will typically stop an attack already underway. Intrusion prevention systems, while connected inline, can stop or redirect attacks preemptively in most cases (Baker, 2004). Of course this extra control comes with a price.

Nicholas Pappas   9

As mentioned previously, the risk introduced with placing either an IDS or IPS inline is related to the likelihood of the system failing resulting in the link being brought down. Some commercial systems will go into failsafe mode where they default to being open and minimize risk of a device failure causing network outage. Security and network analysts should know outage caused by system failure must be avoided if at all possible. The mission of deploying security controls is defeated when the controls themselves are excessively prone to failure. Especially when their failure unintentionally brings down large scale network connectivity.

5. <u>Network Segregation & Trust Zones</u>

Realistically expecting security professionals to completely secure *every* system on a network is unreasonable. Often times, security controls are in direct opposition to functionality inherent with today's feature-rich computing environments. All too often, 100% secure is congruent to 0% usable. An effective strategy to balance security with functionality is with network segregation. The resulting zones are associated with a level of trust based on the sensitivity of the data being processed. Each zone can have a different security policy (Rehman, 2003). This design structure promotes sound security and realistic risk reduction, while at the same time permitting just the right amount of functionality to effectively conduct business.

Figure 1 illustrates how a corporate network may be segregated by functional groups of system users. Finance and accounting staff have legitimate need for direct access to their respective systems during group collaboration efforts, or project

Nicholas Pappas   10

teams efficiently conducting business. For many reasons it may be inadvisable

allowing research and development engineers direct access to systems in the human

relations department. Segregating networks as shown provides a layer of security

and a means for the company to systematically enforce corporate or enterprise

policy. Having a system enforce policy is much more effective than expecting

humans to behave appropriately, or avoid mistakes of unintentionally compromising
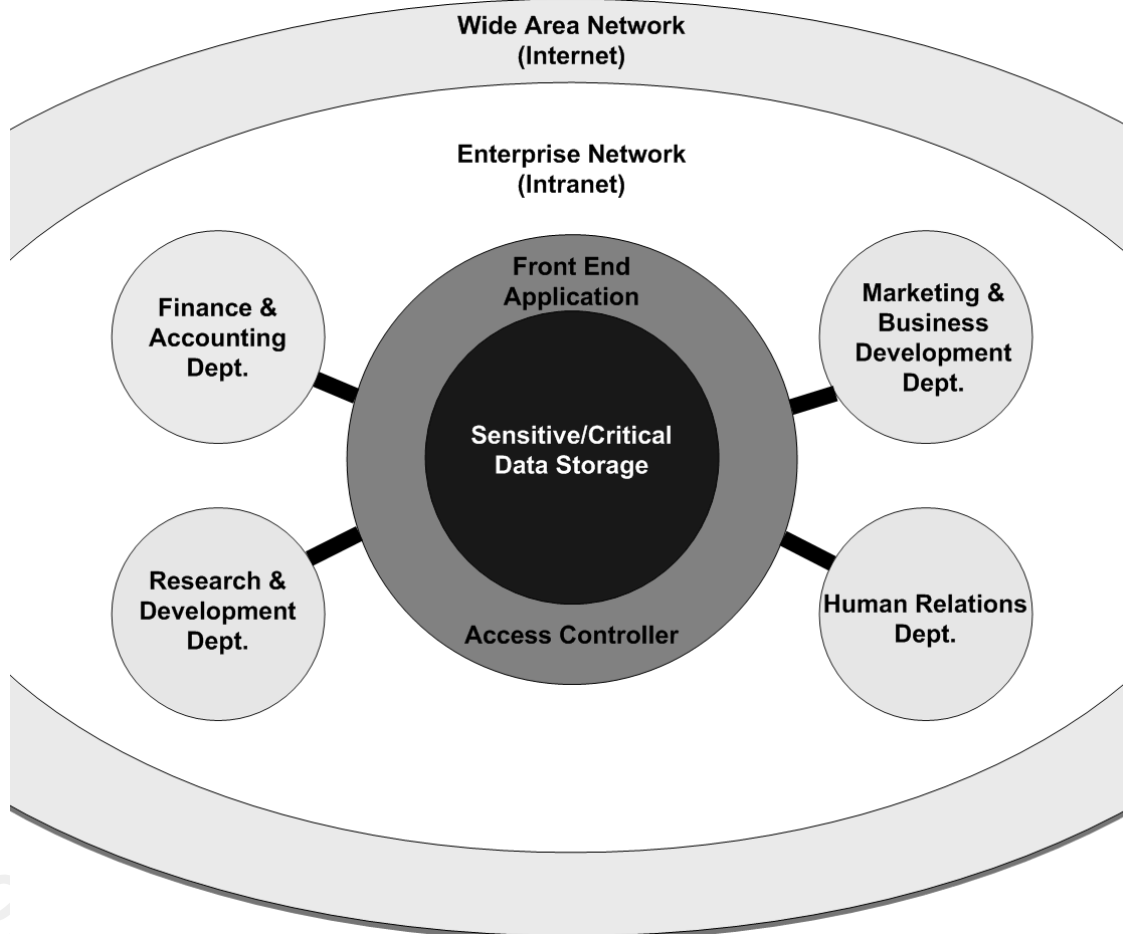

sensitive data.

Figure 1: Typical corporate network zone diagram.

Nicholas Pappas   11

Looking towards the center of Figure 1, you will find concentric circles exhibiting "circles of trust". In this portion of the example, each department has *direct* access to the front end application circle; perhaps in the form of a web application. This front-end application is then utilized to carefully grant or deny access to the organization's most critical data (e.g., file servers, databases). Any four of the sample departments are not capable of gaining direct access to the back end data storage. To view or modify this critically important data, personnel must first go through the middleware responsible for administering the most restrictive permissions. This model follows the principle of least privilege with respect to the innermost data storage zone. That is, giving subjects no more and no less access to objects than is required to exclusively conduct business related tasks (Harris, 2003).

IDS and IPS are great tools to leverage when defining, monitoring, auditing, and enforcing the circumference of each circle. Deploying an IDS and/or IPS at each of the department circles provides a means to monitor and block attempts to violate the policy of the system. If a system in the marketing department attempts to directly access systems in the human relations department it might be a sign of an employee trying to surreptitiously gather payroll information or personnel folders. If multiple systems, from say the research and development department, attempt to access systems in the other three segments it may signal a worm or virus attempting to propagate throughout the enterprise network. Both cases obviously require immediate attention to avoid potential compromise of personnel data or stability of

Nicholas Pappas   12

systems enterprise-wide. Such segregation of a network in turn boosts the ability for response teams to isolate or quarantine system compromises, while the zones not compromised continue conducting business.

Not only does network segregation lend itself to access control, it also helps in throughput management across a large network. Imagine a university network where multiple academic departments (e.g., Arts & Sciences, School of Engineering) are collectively connected to a single backbone network. Figure 2 depicts an architecture where the backbone network provides conduit from one department to another department as well as connectivity for all departments to access the global Internet (i.e., Internet 1 and Internet 2). Network sessions over the backbone will likely outnumber sessions strictly within any single department network. Because of this, the backbone will be best served with network equipment capable of high levels of throughput and low latency. Hardware capable of 10 Gigabit throughput is rather expensive, perhaps too expensive to expect each department to purchase such equipment for their respective segment of the campus network. Without suffering significant performance loss, circuits connecting each department network to the university backbone may be capable of providing 1 Gigabit throughput. Following this model, the local area networks (LAN) within each department may be using 100 Mb equipment. Of course overtime all information technology assets will eventually require an upgrade but the theory behind this model remains valid.
Nicholas Pappas   13

Figure 2: Throughput capabilities of a sizable network.

Consideration of enterprise architecture is important when deploying IPS and

IDS. The reason being that many IPS and IDS will become bottlenecks or points of

congestion when expected to efficiently handle 10 Gigabit throughput. It is unwise

Nicholas Pappas   14

to place such systems on a backbone network capable of pushing large globs of data at extremely high transfer rates. To work around this issue, we place the IDS or IPS between each department level network and the university backbone. Acquiring systems capable of lower throughput will be more cost effective, and a distributed monitoring infrastructure will also provide awareness of network activity in each segment of the greater network. Figure 2 shows such a setup with circuits labeled with their associated data transmission capabilities. The magnified portion of Figure 2 leads us into the next sections covering detailed explanation of IDS/IPS deployment.

This section was admittedly a digression from the main topic. However, the concentric circles and segmentation of the network described here are crucial to understand and consider when planning the logical placement of an IDS or IPS. The concepts explained here are referred to in the remaining sections of the document.

6. <u>Connecting an IDS Device</u>

There are multiple methods one can use to connect an IDS to capture and monitor traffic. In any case, the IDS needs to gather network traffic to be analyzed. Three methods and the benefits of each are briefly discussed here as depicted in Figure 3.

Nicholas Pappas   15
Figure 3: IDS on the edge of a network or zone.

Each part in this illustration consists of two servers, a workstation and an IDS all connected to a piece of network equipment attached to an uplink. The servers and workstation are considered internal assets and the uplink leads to an external network. The red lines represent connections being utilized to monitor traffic, while the black dashed line represents a connection that may be used to manage the IDS

Nicholas Pappas 16

remotely from a system in the internal network.

Part A of Figure 3 shows the IDS connected to either a hub or a switch capable of configuring a SPAN port. On some managed switches, a SPAN port can be configured to send, "...all packets on the network to that port as well as their ultimate destination" (Baker, 2004). With such a configuration, an IDS interface being used to monitor traffic could be connected to a switch yet be able to see all traffic passing through. A network hub intrinsically shares data passing through itself to all of its ports such that any system connected to the hub can see all traffic sourced from or destined to every other system connected to the hub. Using a hub may not be the best option since systems would be capable of intercepting traffic not intentionally sent to them. When using either a hub or switch with SPAN port capabilities, the systems on the internal network are not at the mercy of the IDS having a system failure brining the network down. Making use of a hub or switch SPAN port is a common method of connecting sensors.

The use of a network tap is represented in Part B of Figure 3, which essentially replicates data passed through the wire. Network taps are not commonly found in typical computer networks but may be purchased. Taps are handy when you need to setup a hasty monitoring solution, perhaps to troubleshoot a problem or temporarily deploy an IDS. Overall, a network tap is needed when the network does not have managed switches, is not using hubs, or when putting an IDS inline is out of the question.

Nicholas Pappas   17

The final portion, Part C near the bottom of Figure 3, illustrates an IDS connected inline. This instance includes two connections, shown in red, with one connected to the uplink port of the switch, and the second connected to the external network. In most cases, this is not the best method to use because system failure of the IDS will prevent systems on the internal network from communicating with external systems. Rarely is this an ideal outcome, either way it is certainly an option. The benefit of the inline configuration is a guarantee all packets will be seen by the IDS. Packets are subject to being missed when an IDS is connected to a switch SPAN port, especially when that switch is busy processing a large burst of traffic. Depending on the capability of an inline IDS, a similar burst may lead to congestion of network throughput.

Utilizing a management interface is required if the analysis is to be done remotely. It is possible to simply connect a keyboard and monitor directly to the IDS and manage the system locally from its console. Whilst this may work for a small office, in a large network this is typically not a viable option. The same applies for an IPS which is covered in the following section.

7. Connecting an IPS Device

Intrusion prevention systems are always connected inline. This requirement enables the IPS to drop select packets, and defend against an attack before it takes hold of the internal network (Hansteen, 2008). Here again, in Figure 4, we have red lines showing the network links being used to capture traffic.
Nicholas Pappas   18

IPS connected inline

Figure 4: IPS on the border of a network or zone.

The management interface, shown with a black dashed line, is once again an option

but still commonly used to manage the system remotely. Updating signatures and

otherwise adapting the system to defend against the latest threats is an ongoing

task. Because of this, having an efficient means of administering the device is

important.

The cons of having a system connected inline have been covered earlier in this

document. However, some companies build systems to address this failure

potential. For instance, TippingPoint Technologies Inc. sells products named Zero

Power High Availability devices, designed to pass traffic even in the event their IPS

loses electrical power. As you can imagine, during this type of failure the IPS is

passing unfiltered traffic; much better than dropping all network connectivity. An

optimally configured IPS will block unwanted traffic and, as a consequence, when the

Nicholas Pappas   19

IPS fails the network will typically see an increase in activity. Something for network engineers and intrusion analysts alike to consider when a significant unexplained spike in network activity is noticed on internal networks.

Connecting an IPS is rather simple. After reading this section, you may wonder what can be done to monitor traffic when an IPS either fails entirely, or allows malicious traffic through; perhaps from not being strict enough. A layered approach is introduced in the next section.

8. IDS & IPS Tuple Deployment

Prior to this section, the paper has discussed fundamentals of deploying an IDS or IPS. Now we move on to put these tools together, constructing a layered approach to network monitoring. Connecting these devices appropriately is covered first, we then move into the main point of this document. From a security perspective this is by far the ideal deployment, so let's get started.

Setting the stage for connecting both an IDS and an IPS, a router is introduced between the two sensors as shown in Figure 5. To follow the example, consider the router as defining a trust zone boundary or a network border separating a local area network (LAN) from a wide area network (WAN). Figure 5 then shows the IPS on the external side of the router, with a management link (dashed line) crossing over into the internal network for administration purposes. The IDS is connected in an inline fashion but, as previously mentioned, the IDS does not have to be inline and can be

Nicholas Pappas   20

connected out-of-band which is illustrated below in Figure 6. The IDS is

strategically placed on the internal side of the router. As before, both figures show

red lines depicting connections used to gather data for analysis and/or filtering.

Figure 5: IPS & IDS connected inline.

With the exception of the management interface connected to make remote

administration of the sensors more convenient, the two network interface cards (NIC)

internal to the IPS and IDS (i.e., those connecting the IDS and IPS to the red links) do

not require IP addresses be assigned to them. In fact not having an IP address

assigned to these sensor NIC's makes those interfaces invisible to other systems on

the network. Conversely the rationale behind the reason why the management

interface must have an IP address assigned. The interfaces responsible for collecting

data to be analyzed then merely listen on the wire and pickup electrical impulses
representing data being transmitted.

Nicholas Pappas   21

Figure 6: IPS connected inline, IDS connected to spanning port.

Packets are only concerned with transporting data from source to destination.

Therefore, having two invisible NIC's configured as a bridge leaves the data

untouched as packets travel from the first NIC to the second and carry on their merry

way. When unwanted traffic passes over the invisible IPS bridge, the convivial

journey is abruptly interrupted much like an insect innocently flying about before

being smashed against the windshield of a car traveling at high speeds. For packets

the IPS is programmed to drop, the invisible bridge resembles a thick sheet of glass

unable to be seen. The sender of the dropped packet receives no response, and the

internal network never processes the dropped packet. Such a scenario excites

security professionals charged with defending a network from attack.

That is until their joy comes crashing down when the boss is unable to

communicate with external systems he or she needs to conduct legitimate business

with. When an IPS drops a legitimate packet, it resembles a false positive and is the

Nicholas Pappas   22

effect of an IPS being too stringent. To correct this, the IPS needs to be tuned more conservatively adhering to looser rules while analyzing traffic. When the IPS is configured too conservatively, we witness false negatives as unwanted traffic freely passes through. Obviously we have a conundrum between protecting the network, and keeping business flowing – having both live harmoniously ensures the aforementioned security staff remains employed.

This is where the IDS comes in. Since the IDS is not responsible for dropping packets, the security administrator can set the IDS to be very aggressive. With this higher level of sensitivity the IDS alerts when even the slightest abnormality is present in the traffic being inspected. After spending time going through extraneous alerts the analyst then tunes the IDS to disregard traffic verified to be benign. Conversely, as the analyst finds traffic on the IDS posing a threat, a rule or signature is written and the IPS blocks the threat. This methodology allows analysts the ability to analyze traffic and become familiar with a normal baseline of traffic without interrupting legitimate data flow on the network. Overtime, the diligent analyst will have a sensitive IDS giving very few alerts, as the IPS drops nearly 100% of the unwanted traffic. Any questionable traffic not blocked by the IPS the IDS then alerts on, prompting the analyst for further investigation.
Nicholas Pappas   23

Figure 7: Data state diagram.

The different states of traffic passed through this layered model are exhibited

in Figure 7. State 1 represents data that may or may not be legitimate. State 1 data

is considered neither good nor bad because it has not yet been analyzed. State 2

data has been analyzed and filtered by the IPS. However because of the issue

mentioned above, it may be data the conservatively tuned IPS chose to pass but

whose legitimacy is still questionable. Data in state 3 has been filtered by the IPS

and verified by the more aggressively tuned IDS. Of course any alerts from the IDS

during the verification process may require further investigation by the analyst. For

now it is permitted to pass through. Perhaps the result of a system not configured

properly on the internal network. Of course it may also mean that a new rule needs

Nicholas Pappas   24

to be implemented on the IPS to block similar future attacks. The outcome is a multi-layered approach to monitoring network traffic passing through the boundary of a network or subnetwork.

The main intent is to have the IPS block traffic known to be unnecessary or malicious, while the IDS remains sensitive alerting on traffic that may be difficult to categorize without risking termination of legitimate communication. Conceptually, the IPS is tuned somewhat conservatively and the IDS has a more aggressive tuning. The IDS also provides a checks and balances of its respective IPS. Since the rules implemented in the IPS also exist in the IDS, if the IPS fails the IDS will continue monitoring. If the IDS suddenly sends numerous alerts the IPS is most likely in fail-over mode or has witnessed a system crash. Without a layered approach, traffic would pass through the network unmonitored until the IPS was brought online again.

As shown in figures 5 and 6, the IPS is deployed on the external side of the router or network edge. This allows the IPS to drop packets prior to them hitting the router and prevents the router from having to process extraneous packets thus lightening the load on the routers processor(s). It also provides a means for the analyst to research traffic "in the wild", as well as seeing any probes and scans coming from external systems. If a brute force attack is posed against the IPS, the router avoids having to deal with such nonsense as the IPS actively drops the attack traffic on the floor. Unsuccessful network reconnaissance attempts may be fed into a heuristic of other security controls. Perhaps the organization's competition is in

Nicholas Pappas   25

the midst of staging an attack. Even a minimally tuned IPS would block this traffic, but the analyst monitoring traffic external to his or her network can gain great insight into the latest attacks and threat trends.

Both figures show the IDS placement on the internal side of the edge router. This is required to see traffic being passed from or within the internal network. Especially in the case where the internal network is using Network Address Translation (NAT). Pinpointing internal systems using NAT'd IP addresses would be impossible from the perspective of the IPS since it is on the outside. IDS placement is critical when the analyst needs to track down internal systems sending unwanted traffic. Internal systems sending unwanted traffic may be caused by a system not configured correctly or possibly a compromised system attempting to propagate virus infection. Likewise, if an internal employee is transferring data outside the network, the IDS placed internally will be able to see exactly where this data is coming from and can be configured to report such activity.

Deploying IDS and IPS in pairs is substantially beneficial. Having one without the other will undoubtedly leave gaps in the monitoring of network activity, or possibly lead to ambiguous alerts showing the front end of the NAT'd IP space rather than detailing the specific system responsible for causing questionable traffic. The next section goes over some practical uses of such a setup.

Nicholas Pappas   26

9.Practical Applications and Uses

Using an IDS/IPS paired deployment for researching traffic hitting the external side of a network was briefly discussed in the previous section. What was not mentioned was the fact that having such a system on the external side of the network can actually help other administrators world wide. Consider sharing traffic profile information with collaborative groups such as the SANS Internet Storm Center by submitting activity logs. Or participate in the DSheild Cooperative Network Security Community. DSheild allows you to report malicious activity while remaining anonymous. Often times, system administrators do not know when their respective systems are wreaking havoc outside their network. With so many worms and other automated attacks occurring on the Internet, if your system is being threatened, chances are other innocent systems are being attacked in the same manner.

In organizations required to test applications or carefully examine the effect of new patches prior to being applied to critical servers, it is good practice to setup a test computing environment. In such an environment it is best to ensure traffic is not transmitted outside the test network Having an IDS/IPS paired deployment on the edge of the test environment allows you to prove no traffic has left the environment (implement a drop-all rule on the IPS), as well as the ability to monitor network activity being passed on the inside of the test environment. Ever wonder what anomalous network traffic, if any, the latest prototype of your company's product is causing? How is the latest operating system patch going to effect your

Nicholas Pappas   27

network? Clearly the test environment is an important piece of modern information technology shops.

For information security professionals attempting to evade IDS and IPS detection a test case is very useful. Once such an individual feels they have their IPS and IDS configured just right, they should seek a method to evade their implementation. Likewise with someone who thinks they can sneak in, penetrating the network unnoticed. They should then devise a method to block their covert attack. This is an invaluable means to make even the smartest security professional more capable.

As far as the Blackhats go, setting up a test case of an IDS/IPS to launch attacks against may be beneficial in honing their craft. As most security folks know, being an effective member of any security team involves routinely wearing a black hat (offensive) and then swapping it with that of a lighter shade of grey or white (defensive); not unlike centuries of weapons development versus armor development.

Outside the test environment, larger networks will find the administration of numerous IDS/IPS sensors deployed across their enterprise network a daunting task. Maintaining multiple IDS/IPS pairings is best done by utilizing a central database to store the data gathered. In this case the sensors merely collect data and send it up to a centralized database. Figure 8 shows a high level view of such an implementation.
Nicholas Pappas   28

Figure 8: *Distributed infrastructure of IPS/IDS sensors feeding a centralized database.*

It is important to note, that each IDS/IPS pairing will have their own security policy or rule set. What applies to Segment-1 may not apply to Segment-2 and so on. Furthermore, having the data sent to a centralized location, will minimize the number of highly skilled analysts the organization has to train and keep on the payroll. This will obviously bring about the highest return on investment. On that note, having one instance of data storage cuts down on the number of required systems capable of storing mass amounts of data, not to mention the systems required to conduct analysis on those large data stores. Centralizing analysis efforts also leads to a more consistent interpretation.

The uses mentioned here are just a few of the many. In reality the uses of

Nicholas Pappas   29

such a system are only limited to one's imagination or task orders.

10.Conclusions

As with any security product designed to protect information systems and the data they process, there are limitations. If the intrusion detection or prevention system lacks rules clever enough to detect traffic of interest the system will neither send alerts nor drop packets appropriately. Keeping your signatures updated and maintaining other rules intended to find exactly what you want is an ongoing endeavor.

Another limitation is related to remediation of issues found with a monitoring system. This is a task very difficult to automate. If the organization does not have a viable means of responding to incidents and remediation efforts, being alerted on such events is useless. Often times being able to respond in a timely fashion will make the difference between an entire network virus infection and limiting compromises to the fewest amount of systems. Along those lines, ignorance is bliss. Without response personnel to resolve findings the monitoring systems shed light on, the organization becomes increasingly liable for knowing about a problem but not acting on or resolving it. These systems are not magic, they do require maintenance and will benefit the organization only when coupled with trusted analysts and personnel to help with remediation efforts. This remediation may require modification of system configuration or in-depth investigations into system compromises.

Nicholas Pappas   30

Strategic placement of the monitoring systems is crucial. If you are trying to capture traffic local to your network, you may be missing it if you put it at the network's border. Likewise if you only have one monitoring system, and more than one connection linking your local area network to external networks. One important network device you should be mindful of when selecting the optimal placement of your IDS or IPS is a Virtual Private Network (VPN) concentrator. As traffic travels through a VPN tunnel, it is encrypted and the IDS or IPS will not be capable of conducting adequate analysis.

There are an increasing number of methods to evade intrusion detection. While network intrusion detection and prevention systems are adapting to an ever changing environment, the methods of evasion are as well. We must keep this in mind when making a judgment call with respect to detecting an intrusion. One should not rely too heavily on IDS or IPS logs. Feeling overly confident an intrusion was avoided simply because such activity was not logged may be a costly mistake. On the other hand, assuming the IDS or IPS is correctly classifying "malicious" traffic when in fact the traffic is legit should be avoided as well. Having an analyst skilled in decoding packets will help minimize these mistakes (packet decoding is introduced in the SANS Security Essentials curriculum). In short, having too much trust in any single security product is a recipe for failure.

In conclusion, deploying systems designed to monitor network activity will bring about more awareness of the very nature in how the respective network

Nicholas Pappas   31

behaves, and what threatens its intended function. There is certainly not a shortage

of malicious traffic being transmitted across the Internet. Having a firewall at the

edge of a network is a nice piece of hardware to have protecting internal networks.

However, in information security there are no silver bullets. Network firewalls not

withstanding. It is crucial to have a layered preventive strategy. Defense in depth is

the only reasonable tactic with such adaptable threats being constantly presented to

information systems.

Nicholas Pappas   32

12. Appendix A: Step by Step Build of an IDS/IPS

The following steps have been used to build both IDS and IPS capabilities on a single system. The subject operating system used is OpenBSD. The hardware consists of an Intel based computer with 5 network interface cards installed. The first two cards build an inline bridge and the second pair of cards builds a second inline bridge. The fifth card is used for remote management of the system. OpenBSD was chosen because of their reputation in security and handling of the network stack. The steps listed here pick up after a base install of OpenBSD 4.2 (i386). For more information on how to install OpenBSD please see their web site (http://www.openbsd.org/faq/faq4.html).

While the author does not claim to be an OpenBSD guru, these steps have been verified to build a baseline IDS/IPS and displays alerts via the Basic Analysis and Security Engine (BASE) interface. No benchmarking has been done on the prototype system, and I would highly advise not deploying the resulting system in a production environment without some thorough testing. The prototype also may (does) not have permissions to their most restrictive setting. This appendix was the result of testing out concepts and ideas which were documented in the respective paper and thus the intent of this appendix is to save the reader time in implementing a test case to explore the concepts shared. Reading content is a good start but, for many, having hands on experience will be significantly more beneficial. So let's get started...

Nicholas Pappas   34

General Outline:

1. Acquire OpenBSD ports

2. Network Setup

3. MySQL Installation

4. Snort Installation

5. Oinkmaster Installation

6. Barnyard Installation

7. Integration

8. BASE Installation

9. Baseline pf.conf

NOTE: The details listed below have commands input to the command line interface showing in red font. Any output shown from commands, or file contents will be shown in *italic red font*.

All commands pickup after a base install of OpenBSD 4.2 and assume the root user account is being used. Where possible, permissions were set appropriately for the environment and daemons to run with non-root accounts upon completion of the install process. Many of the packages were installed from the OpenBSD ports collection. You may setup the partitions as you see fit. However, please note that you must have an ample amount of space in your /var partition as that is where the database will be stored. Just as an example, the prototype had 10GB of memory reserved for the /var partition.

Nicholas Pappas   35

Partitions and their sizes for the prototype system:

Filesystem	Size	Mount Point
/dev/wd0a	200MB	/
/dev/wd0h	10GB	/archive
/dev/wd0g	5GB	/home
/dev/wd0d	500MB	/tmp
/dev/wd0f	15GB	/usr
/dev/wd0e	10GB	/var

Acquire OpenBSD Ports

We begin by downloading the ports collection. First find the packages mirror closest to your location and download the cvsup package. You will find a listing of the mirrors at this url (http://www.openbsd.org/ftp.html#ftp). Here is the command used on the prototype:

ftp ftp3.usa.openbsd.org

Login as anonymous (no password required)

cd /pub/OpenBSD/4.2/packages/i386
get cvsup-16.1hp0.tgz
cd /pub/OpenBSD/4.2/
get ports.tar.gz
quit

Now copy the ports.tar.gz file to /usr and unpack it.
cp ports.tar.gz /usr
cd /usr/
tar -xvzf ports.tar.gz
rm ports.tar.gz

Add the cvsup package with the following command as the root user:
pkg_add cvsup-16.1hp0.tgz

This will help keep the ports tree up to date. Now we need to build a cvsup file. The contents of the file called /etc/cvs-supfile are listed here.

Nicholas Pappas   36

--begin file content--
#Example command to use CVSup:
cvsup -g -L 2 /etc/cvs-supfile
#Defaults applicable to all collections
*default host=cvsup.usa.openbsd.org
*default base=/usr
*default prefix=/usr
*default release=cvs
*default tag=OPENBSD_4_2
*default delete use-rel-suffix
*default compress
#Collections
OpenBSD-ports
--end file content--

Commit the following commands to download your collections files. This will take some time depending on your connection to the associated mirror.

cvsup -g -L 2 /etc/cvs-supfile

You should now have OpenBSD's ports in /usr/ports.

Network Setup

First determine how the system indentifies each network interface card (NIC).
ifconfig

Some of the output has been snipped for brevity. However, the 5 NIC's are shown as:

dc0: flags=8802<BROADCAST,SIMPLEX,MULTICAST> mtu 1500
dc1: flags=8802<BROADCAST,SIMPLEX,MULTICAST> mtu 1500
dc2: flags=8802<BROADCAST,SIMPLEX,MULTICAST> mtu 1500
dc3: flags=8802<BROADCAST,SIMPLEX,MULTICAST> mtu 1500
sis0: flags=8843<UP,BROADCAST,RUNNING,SIMPLEX,MULTICAST> mtu 1500

It was decided to use the NIC identified by "sis0" as the administrative interface and the rest are the bridged interfaces. The administrative interface was setup during

Nicholas Pappas   37

the installation process to update the entire system.

sis0 = administrative interface

dc0 = external device non-verified
dc1 = internal device non-verified
dc2 = external device verified
dc3 = internal device verified

See the illustration below for an idea of how this system will be connected and deployed. Please note, the cable connecting the NIC labeled dc1 to the router's interface with an IP address of 192.168.0.3 is a crossover type cable. The rest shown in the image are regular straight through cables. As you can see the router separates two networks. The first network is a Class C identified by 192.168.0.0/24, and the second network is yet another Class C of 192.168.1.0/24. The rest of the document will follow the concept of having 192.168.0.0 as the external or non-trusted network, and 192.168.1.0/24 being considered as the trusted network. Make sure to substitute for your needs where appropriate.
Nicholas Pappas   38

Figure 9: Protoype diagram.

Now that we know how to refer to the NIC's we need to create a file for each. To do this, commit the following commands, while substituting proper identifiers for your NIC's. First make sure these files don't pre-exist (they must only have the word "up" in them for our purposes):

rm /etc/hostname.dc0
rm /etc/hostname.dc1
rm /etc/hostname.dc2
rm /etc/hostname.dc3

Next create the files to tell OpenBSD that we want them up with no IP address.

echo up > /etc/hostname.dc0
echo up > /etc/hostname.dc1
echo up > /etc/hostname.dc2
echo up > /etc/hostname.dc3

Nicholas Pappas   39

Now create two bridges. The first bridge is intended to actually filter traffic deemed malicious or otherwise unwanted, and the second is to verify the filter.

echo "add dc0" >> /etc/bridgename.bridge0
echo "add dc1" >> /etc/bridgename.bridge0
echo "up" >> /etc/bridgename.bridge0

echo "add dc2" >> /etc/bridgename.bridge1
echo "add dc3" >> /etc/bridgename.bridge1
echo "up" >> /etc/bridgename.bridge1

We should now see the following output from these commands:

cat /etc/bridgename.bridge0
add dc0
add dc1
up
cat /etc/bridgename.bridge1
add dc2
add dc3
up

Reboot the system by typing the following command:

reboot

Upon boot completion you should have the packets traveling over both bridges.

Install these packages for convenience:
cd /usr/ports/net/wget
make install

MySQL Installation

First check to see if you already have the required package files

ls /usr/ports/packages/i386/ftp/mysql*
mysql-client-5.0.45.tgz
mysql-server-5.0.45.tgz

Nicholas Pappas   40

If you have these files already, you can skip the next step, otherwise do the following:

cd /usr/ports/databases/mysql
make install

Before we install the server we need to install the p5-DBD-mysql package. To do that commit the following steps:

cd /usr/ports/databases/p5-DBD-mysql
make install

Ok now you should have the required package files.

cd /usr/ports/packages/i386/all
pkg_add mysql-server-5.0.45.tgz
pkg_add mysql-client-5.0.45.tgz

Initial MySQL setup steps for running on OpenBSD. First create the default database:

/usr/local/bin/mysql_install_db

Increase the kernel limit of open files by making the following modification to /etc/sysctl.conf.

echo "kern.maxfiles=4096" >> /etc/sysctl.conf

To automatically start MySQL during system boot append to /etc/rc.local. You will have to edit the file at /etc/rc.local in this case. At the bottom of the file, add the contents shown here.

```
#Added to start MySQL during boot.
if [ -x /usr/local/bin/mysqld_safe ]; then
    su -c mysql root -c '/usr/local/bin/mysqld_safe --log-error >/dev/null 2>&1 &'
    mkdir -p /var/run/mysql
    ln -s /var/www/var/run/mysql/mysql.sock /var/run/mysql/mysql.sock
    echo -n ' mysql'
    sleep 5
    echo ' done'
fi
```

Nicholas Pappas   41

To make the above entry into /etc/rc.local work properly, we'll need to add to the /etc/login.conf and then rebuild the login.conf.db as described here:

First open /etc/login.conf and add:

MySQL class

mysql:\
     :openfiles-cur=1024:\
     :openfiles-max=2048:\
     :tc=daemon:

Then rebuild the login.conf with:

cap_mkdb /etc/login.conf

Fix some permissions issues so that we can get mysqld started and set a password.

mkdir -p /var/run/mysql

chown -R _mysql /var/run/mysql

Manually start the MySQL daemon for purposes of completing the install.

su -c mysql root -c '/usr/local/bin/mysqld_safe'

/usr/local/bin/mysqladmin -u root password 'secret-pass'

/usr/local/bin/mysqladmin -u root -h centaur.sci-fer.com password 'secret-pass'

At this time now MySQL is installed, it's now time to configure it specifically for our purposes. Shutdown the MySQL daemon.

mysqladmin shutdown -p

<enter MySQL root password>

Next copy the configuration file we'll be using.

cp /usr/local/share/mysql/my-large.cnf /etc/my.cnf

Now do some preparatory steps for our my.cnf file.

mkdir -p /var/www/var/run/mysql

chown _mysql._mysql /var/www/var/run/mysql

Next step is to configure the MySQL Daemon such that it injects the socket in the proper location. To do this we need to make two subtle modifications. First change

Nicholas Pappas   42

the client section in /etc/my.cnf from this:

[client]
#password   = your_password
port   = 3306
socket   = /var/run/mysql/mysql.sock

To this:

[client]
#password   = your_password
port   = 3306
socket   = /var/www/var/run/mysql/mysql.sock

Likewise, the mysqld section needs to be changed from this:

The MySQL server
[mysqld]
port   = 3306
socket   = /var/run/mysql/mysql.sock

To this:

The MySQL server
[mysqld]
port   = 3306
socket   = /var/www/var/run/mysql/mysql.sock

Now when we force the Snort process into the chroot'd environment it will be able to reach the mysql.sock socket file. Ok time for a reboot to test the startup settings we have thus far. After the system boots, you should have the MySQL server running. Connect to the MySQL server with the following:

mysql –u root –p

Next we should tidy up a bit.

mysql> drop database test;

Nicholas Pappas   43

Now we have a clean slate. Check for something very similar to the following output.

mysql> show databases;
```
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
+--------------------+
2 rows in set (0.00 sec)
```

mysql> quit;

Snort Installation

Before we create the Snort database we build and install Snort from ports. To do that follow these steps.

cd /usr/ports/net/snort

export FLAVOR=mysql

make install

NOTE: At the end of the compile it states how to invoke Snort properly

--start of snip--

snort-2.6.0.2p1-mysql: complete
--- snort-2.6.0.2p1-mysql ------------------
An up-to-date set of rules is needed for Snort to be useful as an IDS.
These can be downloaded manually or net/oinkmaster can be used to
download the latest rules from several different sources.

It is recommended that snort be run as an unprivileged chrooted user.
A _snort user/group and a log directory have been created for this
purpose. You should start snort with the following options to take
advantage of this:

  -c /etc/snort/snort.conf -u _snort -g _snort -t /var/snort -l /var/snort/log
--end of snip--

Now you should have a user and group at the OS level added with the name of "_snort". To check this run:

tail –n 1 /etc/passwd

_snort::557:557:Snort Account:/nonexistent:/sbin/nologin*

Nicholas Pappas   44

Ok time to build the snort database.

cd /usr/ports/net/snort/w-snort-2.6.0.2p1-mysql/snort-2.6.0.2/schemas

mysql -u root -p

Enter password:
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.0.33-log OpenBSD port: mysql-server-5.0.33
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> CREATE DATABASE snort;
Query OK, 1 row affected (0.05 sec)

mysql> connect snort

Connection id: 4
Current database: snort

mysql> show tables;
Empty set (0.02 sec)

mysql> source create_mysql;
--output snipped for brevity--

Nicholas Pappas   45

```
mysql> show tables;

+------------------+
| Tables_in_snort  |
+------------------+
| data             |
| detail           |
| encoding         |
| event            |
| icmphdr          |
| iphdr            |
| opt              |
| reference        |
| reference_system |
| schema           |
| sensor           |
| sig_class        |
| sig_reference    |
| signature        |
| tcphdr           |
| udphdr           |
+------------------+
16 rows in set (0.00 sec)
```

mysql> GRANT INSERT, SELECT, CREATE, UPDATE, DELETE on snort.* to \
snort@localhost IDENTIFIED BY 'secret-password';

mysql> quit;

At this time, we should have a snort database created, and a user named "snort" which will be used to send events to the MySQL database. Now do these steps to ensure Snort will come up automatically:

chmod 4755 /usr/local/bin/snort
chgrp _snort /usr/local/bin/snort

Although were are not quite done with the Snort setup yet, let's move on.

Nicholas Pappas   46

Oinkmaster Installation

Next we'll install the Oinkmaster package to maintain our Snort rules files. Run the `make install` from ports after setting the FLAVOR environment variable back to null.

export FLAVOR=
cd /usr/ports/net/oinkmaster
make install

Now you will probably want to register with Snort to have Oinkmaster keep your rules up to date. Register at https://www.snort.org/pub-bin/register.cgi. Here is a snippet from the oinkmaster.conf file which explains this requirement.

--start of snip--
As of March 2005, you must register on the Snort site to get access
to the official Snort rules. This will get you an "oinkcode".
You then specify the URL as
http://www.snort.org/pub-bin/oinkmaster.cgi/<oinkcode>/<filename>
For example, if your code is 5a081649c06a277e1022e1284b and
you use Snort 2.4, the url to use would be (without the wrap):
http://www.snort.org/pub-bin/oinkmaster.cgi/
5a081649c06a277e1022e1284bdc8fabda70e2a4/snortrules-snapshot-2.4.tar.gz
See the Oinkmaster FAQ Q1 and http://www.snort.org/rules/ for
more information.
--end of snip--

First make sure you know which version of Snort you have.

snort -V

At the time of this writing, the OpenBSD ports collection contained version 2.6. Once you have your Oinkcode and know the version of Snort you have installed, modify the following line in /etc/oinkmaster.conf

url = http://www.snort.org/pub-bin/oinkmaster.cgi/<oinkcode>/snortrules-snapshot-2.4.tar.gz

to be

url = http://www.snort.org/pub-bin/oinkmaster.cgi/YOUR-CODE/snortrules-

Nicholas Pappas   47

snapshot-2.6.tar.gz

Save the file and then give it a test by running Oinkmaster manually.

cd /etc/snort/rules

oinkmaster –o .

You should now have the rules files populated in the /etc/snort/rules directory. To check this list the files in that directory. You will see the files containing signatures if Oinkmaster is working properly.

ls

To learn more about Oinkmaster it is recommended that you read the documentation, specifically the README file located on this page: http://oinkmaster.sourceforge.net/readme.shtml

NOTE: At the time of this writing, there appears to be something wrong with the syntax of the telnet rules so you may need to remove that rule or otherwise fix the syntax. To remove the telnet rules you should modify your /etc/snort.conf file by commenting out the line including telnet.rules

Change:

include $RULE_PATH/telnet.rules

So that it looks like:

 # include $RULE_PATH/telnet.rules

Ok, Oinkmaster is installed. You can use this program manually by using the commands shown next. Or you can setup a cronjob to do it for you on a routine basis.

cd /etc/snort/rules

oinkmaster –o .

Barnyard Installation

Barnyard is a nice program that takes unified output from programs like Snort and inputs log or event information into a useful format. For this prototype, we want

Nicholas Pappas   48

Barnyard to take the unified output from Snort and insert it into the MySQL database.

cd /usr/local/share

wget http://www.snort.org/dl/barnyard/barnyard-0.2.0.tar.gz

tar -xvzf barnyard-0.2.0.tar.gz

rm barnyard-0.2.0.tar.gz

cd barnyard-0.2.0

To prevent the loss of MySQL connection(s). We need to patch Barnyard source before compiling it.

cd barnyard-0.2.0

Now edit the file named "src/output-plugins/op_acid_db.c" by adding the following just before a line containing: "while(mysql_ping(mysql) != 0)"

mysql->reconnect=1;

The final function should look exactly like this:

```
--start of snip--
int MysqlExecuteQuery(MYSQL *mysql, char *sql)
{
  int mysqlErrno;
  int result;
  while((result = mysql_query(mysql, sql) != 0))
  {
    mysqlErrno = mysql_errno(mysql);
    if(mysqlErrno < CR_MIN_ERROR)
    {
      if(pv.verbose)
        LogMessage("MySQL ERROR(%i): %s.  Aborting Query\n",
              mysql_errno(mysql), mysql_error(mysql));
      return result;
    }
    if((mysqlErrno == CR_SERVER_LOST)
        || (mysqlErrno == CR_SERVER_GONE_ERROR))
    {
      LogMessage("Lost connection to MySQL server.  Reconnecting\n");
      /* MySQL reconnect line inserted to fix the MySQL idle disconnect issue. */
      mysql->reconnect=1;
```

Nicholas Pappas   49

```
        while(mysql_ping(mysql) != 0)
        {
            if(BarnyardSleep(15))
                return result;
        }
        LogMessage("Reconnected to MySQL server.\n");
    }
    else
    {
        /* XXX we could spin here, but we do not */
        LogMessage("MySQL Error(%i): %s\n", mysqlErrno, mysql_error(mysql));
    }
  }
  return result;
}
```
--end of snip--

Ok now we're clear to compile Barnyard.

./configure –enable-mysql

make

make install

cp /usr/local/share/barnyard-0.2.0/etc/barnyard.conf /etc/snort/

Integration

Now we need to integrate many of the applications we have installed thus far.

cd /etc/snort

You will want to familiarize yourself with the /etc/snort/snort.conf file. The file itself is well commented and discussed in the Official Snort Manual (http://www.snort.org/docs/snort_htmanuals/htmanual_2615/). To get you and your system started, the following variables need to be set. Open snort.conf with vi or some other editor. If you choose an editor other than vi you may have to install it from ports.

Change:
"var HOME_NET any"
to:

Nicholas Pappas   50

"var HOME_NET [192.168.1.0/24,192.168.0.3]"

Also Change:

"var EXTERNAL_NET any"

to:

"var EXTERNAL_NET !$HOME_NET"

To make Snort send alerts through Barnyard we uncomment the following lines:

 # output alert_unified: filename snort.alert, limit 128
 # output log_unified: filename snort.log, limit 128

Such that they look like this:

output alert_unified: filename snort.alert, limit 128
output log_unified: filename snort.log, limit 128

Save your snort.conf changes and exit your favorite editor. Now we'll need to make two configuration files. One for the first bridge and the other for the second bridge.

First let's make barnyard-bridge0.conf

cd /etc/snort/

cp barnyard.conf barnyard-bridge0.conf

Now make the following modifications:

Change:

 # config daemon

to this

config daemon

Change:

#config localtime

to this

config localtime

Change:

config interface: fxp0

to

config interface: bridge0

Change:

output alert_fast

to

 # output alert_fast

Change:

Nicholas Pappas   51

output log_dump
to
 # output log_dump
Change:
config hostname: snorthost
to reflect your Snort sensor machine (which may very well be localhost)
config hostname: localhost
Now enable the following output plugin lines
#output alert_acid_db: mysql, sensor_id 1, database snort, server localhost, user root
 # output log_acid_db: mysql, database snort, server localhost, user root, detail full
Such that it looks similar to this (ensure you use the same password you set for the snort account in MySQL):
output alert_acid_db: mysql, sensor_id 0, database snort, server localhost, user snort,
password secret-pass
*output log_acid_db: mysql, database snort, server localhost, user snort, password *
secret-password, detail full

Ok now save the barnyard-bridge0.conf file and make a copy of barnyard.conf for the next config file we'll need. In the next file, we'll make similar changes. The only difference is swapping bridge0 for bridge1 and making sensor_id 0 set to sensor_id1
cp barnyard.conf barnyard-bridge1.conf

Now edit that file.
vi barnyard-bridge1.conf

Change:
 # config daemon
to this
config daemon
Change:
#config localtime
to this
config localtime
Change:
config interface: fxp0
to
config interface: bridge0

Nicholas Pappas   52

Change:

output alert_fast

to

 # output alert_fast

Change:

output log_dump

to

 # output log_dump

Change:

config hostname: snorthost

to reflect your Snort sensor machine (which may very well be localhost)

config hostname: localhost

Now enable the following output plugin lines

#output alert_acid_db: mysql, sensor_id 1, database snort, server localhost, user root
 # output log_acid_db: mysql, database snort, server localhost, user root, detail full

Such that it looks similar to this (ensure you use the same password you set for the

snort account in MySQL):

output alert_acid_db: mysql, sensor_id 1, database snort, server localhost, user snort,
password secret-pass
*output log_acid_db: mysql, database snort, server localhost, user snort, password *
secret-password, detail full

Ok you should now save the barnyard-bridge1.conf file

Once again the only differences between barnyard-bridge0.conf and

barnyard-brdige1.conf are on the "config interface" line and the line starting with

"output alert_acid_db" where the id numbers are either '0' or '1'. Set permissions

(need to protect the password content):

chmod 640 barnyard*.conf

Copy the maps over.

cd /usr/ports/net/snort/w-snort-2.6.0.2p1/snort-2.6.0.2/etc/

cp gen-msg.map /etc/snort/

cp sid-msg.map /etc/snort/

Nicholas Pappas   53

Insert the following into /etc/rc.local, this will startup both instances of Snort and Barnyard. Please notice that this content goes <u>below</u> the entry we made earlier for MySQL.

--start of snip--

 # Added to start Barnyard on bridge 0 during boot after the db is up but
 # before Snort is brought up.
if [-x /usr/local/bin/barnyard]; then
*/usr/local/bin/barnyard -D -w barn.waldo-0 -c /etc/snort/barnyard-bridge0.conf *
*-d /var/snort/log/bridge0 -g /etc/snort/gen-msg.map -s /etc/snort/sid-msg.map *
-f snort.log -X /tmp/barnyard-bridge0.pid
echo ' barnyard bridge 0'
fi

 # Added to start Barnyard on bridge 1 during boot after the db is up but
 # before Snort is brought up.
if [-x /usr/local/bin/barnyard]; then
*/usr/local/bin/barnyard -D -w barn.waldo-1 -c /etc/snort/barnyard-bridge1.conf *
*-d /var/snort/log/bridge1 -g /etc/snort/gen-msg.map -s /etc/snort/sid-msg.map *
-f snort.log -X /tmp/barnyard-bridge1.pid
echo ' barnyard bridge 1'
fi

 # Added to start the first Snort sensor during boot after the db is brought up.
if [-x /usr/local/bin/snort]; then
*/usr/local/bin/snort -c /etc/snort/snort.conf -u _snort -g _snort -t /var/snort -l *
/var/snort/log/bridge0 -G 0 -i bridge0 -D
sleep 5
echo ' snort bridge 0'
fi

 # Added to start the second Snort sensor during boot after the db is brought up.
if [-x /usr/local/bin/snort]; then
*/usr/local/bin/snort -c /etc/snort/snort.conf -u _snort -g _snort -t /var/snort -l *
/var/snort/log/bridge1 -G 1 -i bridge1 -D
sleep 5
echo ' snort bridge 1'
fi
--end of snip--

Nicholas Pappas   54

Finally some minor steps before we reboot for another test.

mkdir /var/snort/log/bridge0

mkdir /var/snort/log/bridge1

touch /etc/snort/rules/local.rules

chown -R _snort /etc/snort

Reboot and hope for the best. This is a critical test. Upon reboot you should have two snort daemons running and their respective barnyard's should be inserting events found into MySQL. Now you should check to make sure you have snort running, two of them actualy.

ps aux | grep snort

In the resulting output you should see two processes being run by _snort. If not check the /var/log/daemon log for clues and make sure this is working after a reboot. It may take a couple tries but it's crucial to ensure your system boots appropriately.

BASE Installation

To start the web interface we need to make some changes to rc.conf and create an SSL cert. In your /etc/rc.conf file change:

#httpd_flags=NO   # for normal use: "" (or "-DSSL" after reading ssl(8))
to
httpd_flags=-DSSL   # for normal use: "" (or "-DSSL" after reading ssl(8))

Create a self-signed SSL certificate. For more information please read the following web page http://www.openbsd.org/faq/faq10.html#HTTPS. While there are validation related issues with self-signed certificates, this should get your system up and running. If you put this system into a production deployment, you should really considering obtaining certificates from a trusted Certifying Authority.

Until then, commit the following steps to move forward.

Nicholas Pappas   55

Create your server key:

openssl genrsa -out /etc/ssl/private/server.key 1024

Next create a signing request:

openssl req -new -key /etc/ssl/private/server.key -out /etc/ssl/private/server.csr

You will be prompted to answer some questions on this step. Now generate a self-signed certificate:

openssl x509 -req -days 365 -in /etc/ssl/private/server.csr \
        -signkey /etc/ssl/private/server.key -out /etc/ssl/server.crt

If you would like to reboot again, you can then test the SSL functionality with opening the following url up with a browser on the trusted network.

https://<system's IP>

The result should show Apache's garden variety "It Worked" page. Now remove test web content from your filesystem (you don't need it).

rm -r /var/www/htdocs/*

Installed required packages from OpenBSD's ports. NOTE: Some of these may have been installed by steps noted above. Even if they have been installed, it doesn't hurt to (re)build each of these packages as shown below.

cd /usr/ports/databases/p5-DBI
make install

cd /usr/ports/databases/p5-DBD-mysql
make install

cd /usr/ports/print/freetype
make install

cd /usr/ports/devel/gettext
make install

Nicholas Pappas   56

cd /usr/ports/converters/libiconv
make install

cd /usr/ports/converters/recode
make install

cd /usr/ports/graphics/tiff
make install

cd /usr/ports/www/php4
make install
NOTE: Installing php4 from ports takes a while.
cd /usr/ports/graphics/gd
make install

cd /usr/ports/graphics/png
make install

cd /usr/ports/graphics/jpeg
make install

cd /usr/ports/packages/i386/all
pkg_add php4-pear-4.4.1p2.tgz

Activate PHP
/usr/local/sbin/phpxs -s
cp /usr/local/share/examples/php4/php.ini-dist /var/www/conf/php.ini

Open /var/www/conf/httpd.conf with you favorite editor and uncomment the line
#AddType application/x-httpd-php .php
so that it looks like this:
AddType application/x-httpd-php .php

Nicholas Pappas   57

Add more packages.

cd /usr/ports/packages/i386/all

pkg_add -v php4-gd-4.4.1p5.tgz

/usr/local/sbin/phpxs -a gd

pkg_add -v php4-mysql-4.4.1p1.tgz

/usr/local/sbin/phpxs -a mysql

cd /var/www/htdocs

wget http://easynews.dl.sourceforge.net/sourceforge/secureideas/base-1.3.9.tar.gz

tar -xvzf base-1.3.9.tar.gz

rm base-1.3.9.tar.gz

ln -s base-1.3.9 base

cd base

cp base_conf.php.dist base_conf.php

chmod 640 /var/www/htdocs/base/*.php

chown www /var/www/htdocs/base/*.php

Set the following variables in the file at /var/www/htdocs/base/base_conf.php. These variables are in different locations of this file. They are gathered here for brevity.

$BASE_urlpath = '/base';
$DBlib_path = '/htdocs/adodb';
$alert_dbname   = 'snort';
$alert_host   = 'localhost';
$alert_port   = '';
$alert_user   = 'snort';
$alert_password = 'secret-password';

Save and exit. Next we activate what we need in PEAR.

pear upgrade --force http://pear.php.net/get/Archive_Tar-1.3.2.tgz

http://pear.php.net/get/XML_Parser http://pear.php.net/get/Console_Getopt

pear upgrade --force http://pear.php.net/get/PEAR-1.4.3.tar

pear upgrade PEAR

pear install Structures_Graph

pear install Image_Graph-alpha Image_Canvas-alpha Image_Color Numbers_Roman

Nicholas Pappas   58

```
pear install --alldeps  channel://pear.php.net/Numbers_Words-0.15.0
pear install --alldeps  channel://pear.php.net/Image_Graph-0.7.2
cp -r /var/www/pear/Image /var/www/pear/lib/Image/
```

Install ADODB
```
cd /var/www/htdocs/
wget http://superb-east.dl.sourceforge.net/sourceforge/adodb/adodb495a.tgz
tar -xvzf adodb495a.tgz
rm adodb495a.tgz
```

Install JPGraph
```
cd /var/www/htdocs/
wget http://hem.bredband.net/jpgraph/jpgraph-1.22.tar.gz
tar -xvzf jpgraph-1.22.tar.gz
rm jpgraph-1.22.tar.gz

mkdir /var/www/tmp
chown -R www /var/www/tmp
```

Now is a good time to restart httpd
```
/usr/sbin/apachectl stop
/usr/sbin/apachectl startssl
```

Now create the ACID database so that barnyard starts up successfully.   From the trusted network, you need to open the link shown below. Open a browser and go to https://<your IP>/base/base_db_setup.php

Then click the button labeled "Create BASE AG" in the "Status" column. Now create a user by going to the web interface and clicking on "Administration" and then click "Create a user". After filling in the dialog boxes, choose the appropriate role and click "Submit Query". Now make one last modification to the file at /var/www/htdocs/base/base_conf.php and change the following from:

Nicholas Pappas   59

$Use_Auth_System = 0;
to
$Use_Auth_System = 1;

This simple step enables some very basic authentication and provides yet another layer for the bad guys to go through if they want to help monitor your traffic.

Baseline pf.conf

To make PF start during system boot we need to modify /etc/rc.conf and change:
pf=NO   # Packet filter / NAT
to
pf=YES   # Packet filter / NAT

You will want to modify your /etc/pf.conf file. The capabilities of this file are way out of the scope of this tutorial. However there are a lot of online resources and recently a book was published titled "The Book of PF" by Peter Hansteen. A great resource to have on hand. Also a great introduction to PF can be found at:
http://www.openbsd.org/faq/pf/
For this setup. Here is a snippet of a baseline /etc/pf.conf file. This should help you understand how we are treating the two bridges (with Snort) and running PF on the network interface labeled dc1 (your network card's manufacturer may have a different label for the interface).

Nicholas Pappas   60

```
--start of snip--
#
# Simple pf.conf file
#
# See pf.conf(5) and /usr/share/pf for syntax and examples.
## MACROS

# inboard_int: The internal side of the external bridge
# Will be doing most of the filtering on this interface
inboard_int = dc1

# mgt_int: The NIC used for managing.
# Need to restrict as much as possible on this one.
mgt_int = sis0

# Other interfaces:
other_int = "{ dc0, dc2, dc3 }"

# Trusted IP's
trusted = "{ 192.168.1.0/24, 192.168.0.3 }"
notrust = "192.168.0.1/24"

# The internal trusted zone
internal_lan = "192.168.1.0/24"

# Outside the trusted zone && notrust zone
external_wan = "!192.168.0.0/23"

client_out = "{ ftp, ssh, 25, domain, pop3, auth, nntp, http, https, cvspserver, 993,\ 2628,
5999, 8000, 8080 }
###############################################################
# TABLES
###############################################################
table <bruteforce> persist

###############################################################
# Other
###############################################################
## Only filter on specific interfaces
set skip on $other_int

###############################################################
```

```
# FILTER RULES

#################################################################
# Default deny policy
block all
block quick from <bruteforce>

#################################################################
# Rules for the management interface
#################################################################
pass quick on $mgt_int inet proto { tcp, udp } from $trusted to any port \
       { ssh, domain, http, https } keep state (max-src-conn 20, max-src-conn-rate 10/5, \
       overload <bruteforce> flush global)
pass quick on $mgt_int inet proto { tcp, udp } from 192.168.1.4 to any port $client_out

#################################################################
# Rules for the bridge
#################################################################
pass quick on $inboard_int inet proto { tcp, udp } from $trusted to any port { domain, ntp }
pass on $inboard_int inet proto tcp from $trusted to any port $client_out
pass on $inboard_int inet proto { tcp, udp } from any to $trusted port 22 \
       keep state (max-src-conn 20, max-src-conn-rate 10/5, overload <bruteforce> \
       flush global)
pass on $inboard_int inet proto { tcp, udp } from any to $trusted port 443 \
       keep state (max-src-conn 20, max-src-conn-rate 10/5, overload <bruteforce> flush
global)
```

--end of snip--

This pf.conf file only allows ssh (port 22) and https (port 443) inbound from the external network (no trust) to the internal network (trusted). As a reminder, on the prototype system, the network card labled sis0 wasdesignated to be the management interface. Make substitutions as needed. While you are in the beginning stages of configuring your pf.conf file. It is recommended to have a monitor and keyboard (aka console) handy, in case you lock yourself out from the network perspective. PS to disable pf, as root you use:

pfctl –d

The rest is left for the user to explore...
Now you are ready to reboot and start the journey!

Nicholas Pappas   62
